- 4 Discussion**

1

Introduction

Background

Accidental Rip currents

- The social issue at the Haeundae beach
- Rip currents occur repeatedly and sweep away swimmers
- Rip currents are generated due to the longshore variations of wave energy caused by alongshore non-uniformities
- Strong jet-like flow evolves through the lower-energy zone (rip-channel)

Daecheon beach in west coast of Korea

Most famous beach

- The biggest beach on the west coast of Korea
- Soft sand composed of tiny bits of eroded shells
- **'Boryeong Mud Festival'** attracts visitors from throughout the world in July every year
- Length: 3.5 km / Width: 100 m

Daecheon beach in west coast of Korea

Location , Bathymetry and Observation

- submerged rocks are located near the wave breaking zone
- CCTV monitoring system has been operated since 2013

Rip current at Daecheon beach

- Question whether rip currents can occur at beaches of the west coast of the Korea
- The events of rip current occurred at the Daecheon beach
- The coast characterized by dissipative beach profiles with very gentle slope and macro tides

Snapshots of rip current occurrence at the Daecheon beach, 2012 (Choi and Kim, 2016)

Observation

: 0.6m wave height, 6 s wave period, and 4m tidal elevation about MSL

Rip current at Daecheon beach

Snapshots of rip current occurrence at the Daecheon beach, 2014~2015

Observation

: 0.6~1.5m wave height, 6~10 s wave period, and 3~6m tidal elevation

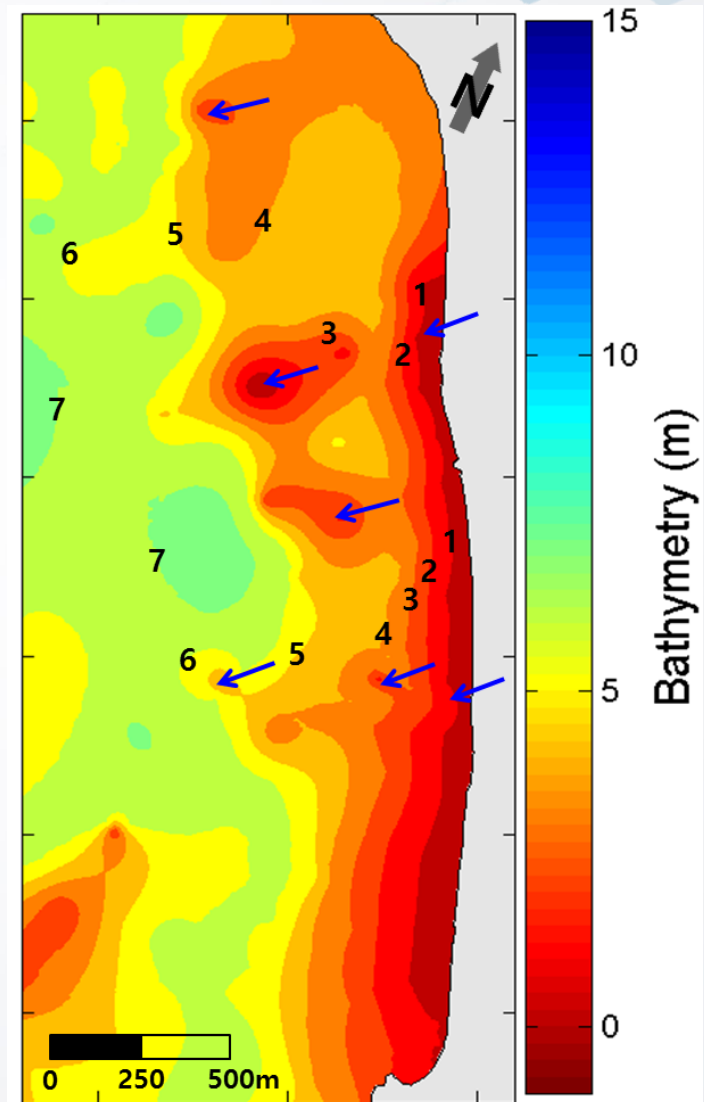

2 Numerical Simulation

Numerical simulations for rip current generation

SWASH model

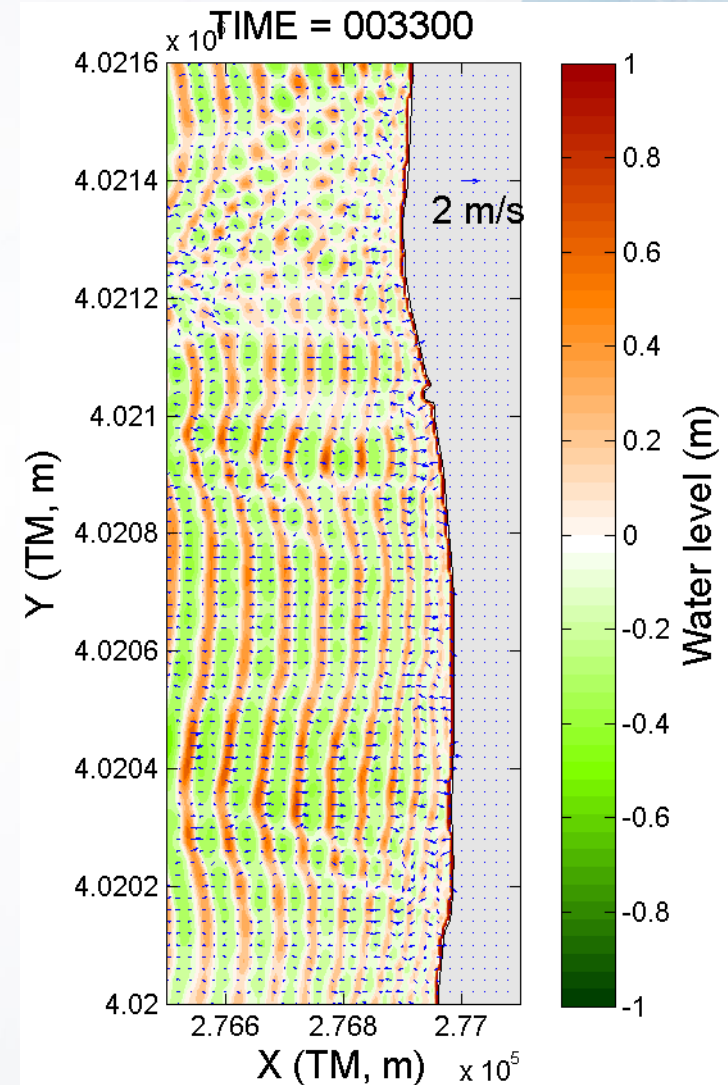

- Based on the non-linear shallow water equations with non-hydrostatic pressure model
- SWASH is very likely to be competitive with the Boussinesq-type wave models.
- One of the most advanced model for simulating rapid wave-induced current (i.e., rip current)

Topography of Daechon beach at medium tide, which was rotated 25 degree in clockwise direction

Model setup

- $dx=dy=5m$ (grid size)
- $nx=261, ny=611$ (1300m x 3000m)
- Time step : 0.005 s, run : 60 min
- Friction coefficient $n = 0.019$
- Mean tide level condition
- Test cases for monochromatic wave conditions
 - : wave heights (1.0, 1.5, 2.0m)
 - wave periods (8.0, 10.0, 12.0s)
 - wave directions (SW, WSW, SSW, WNW)
- Wave-induced rip current are computed by averaging velocities for the last six-wave-periods.

Sample case simulated snap-shot of free surface displacement(shading) and currents

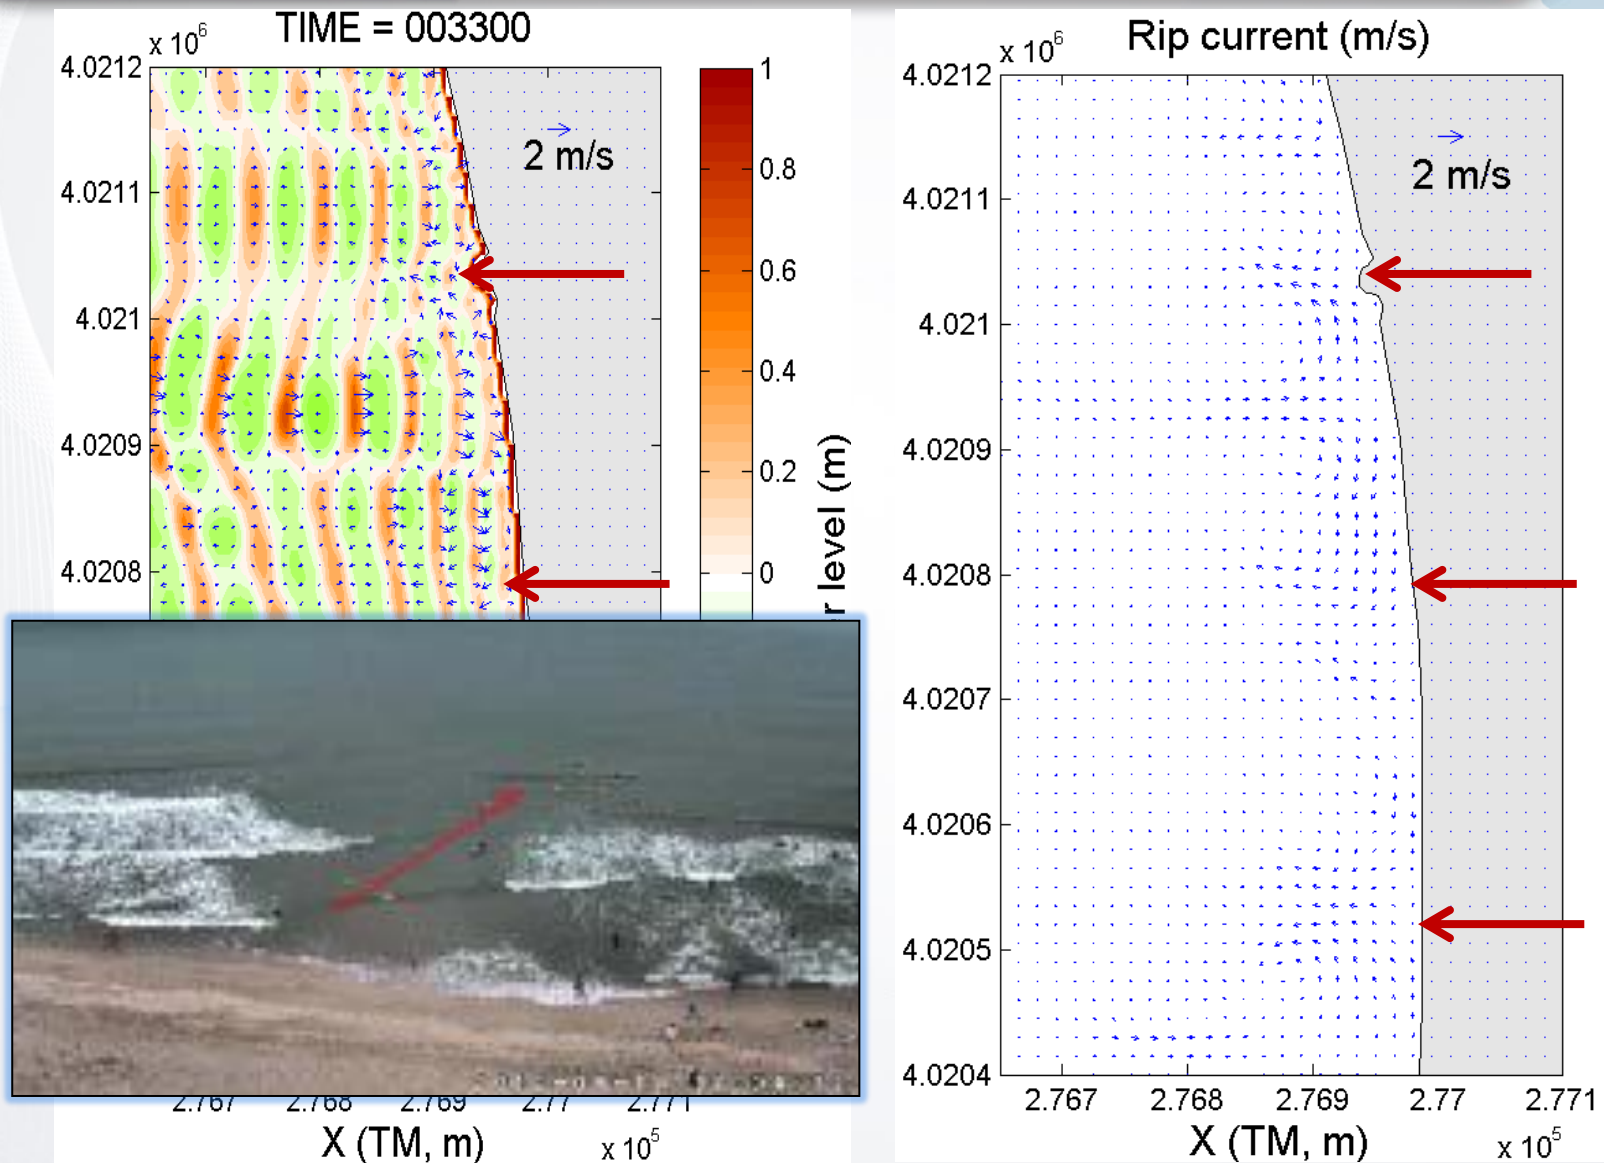

3 Simulation Results

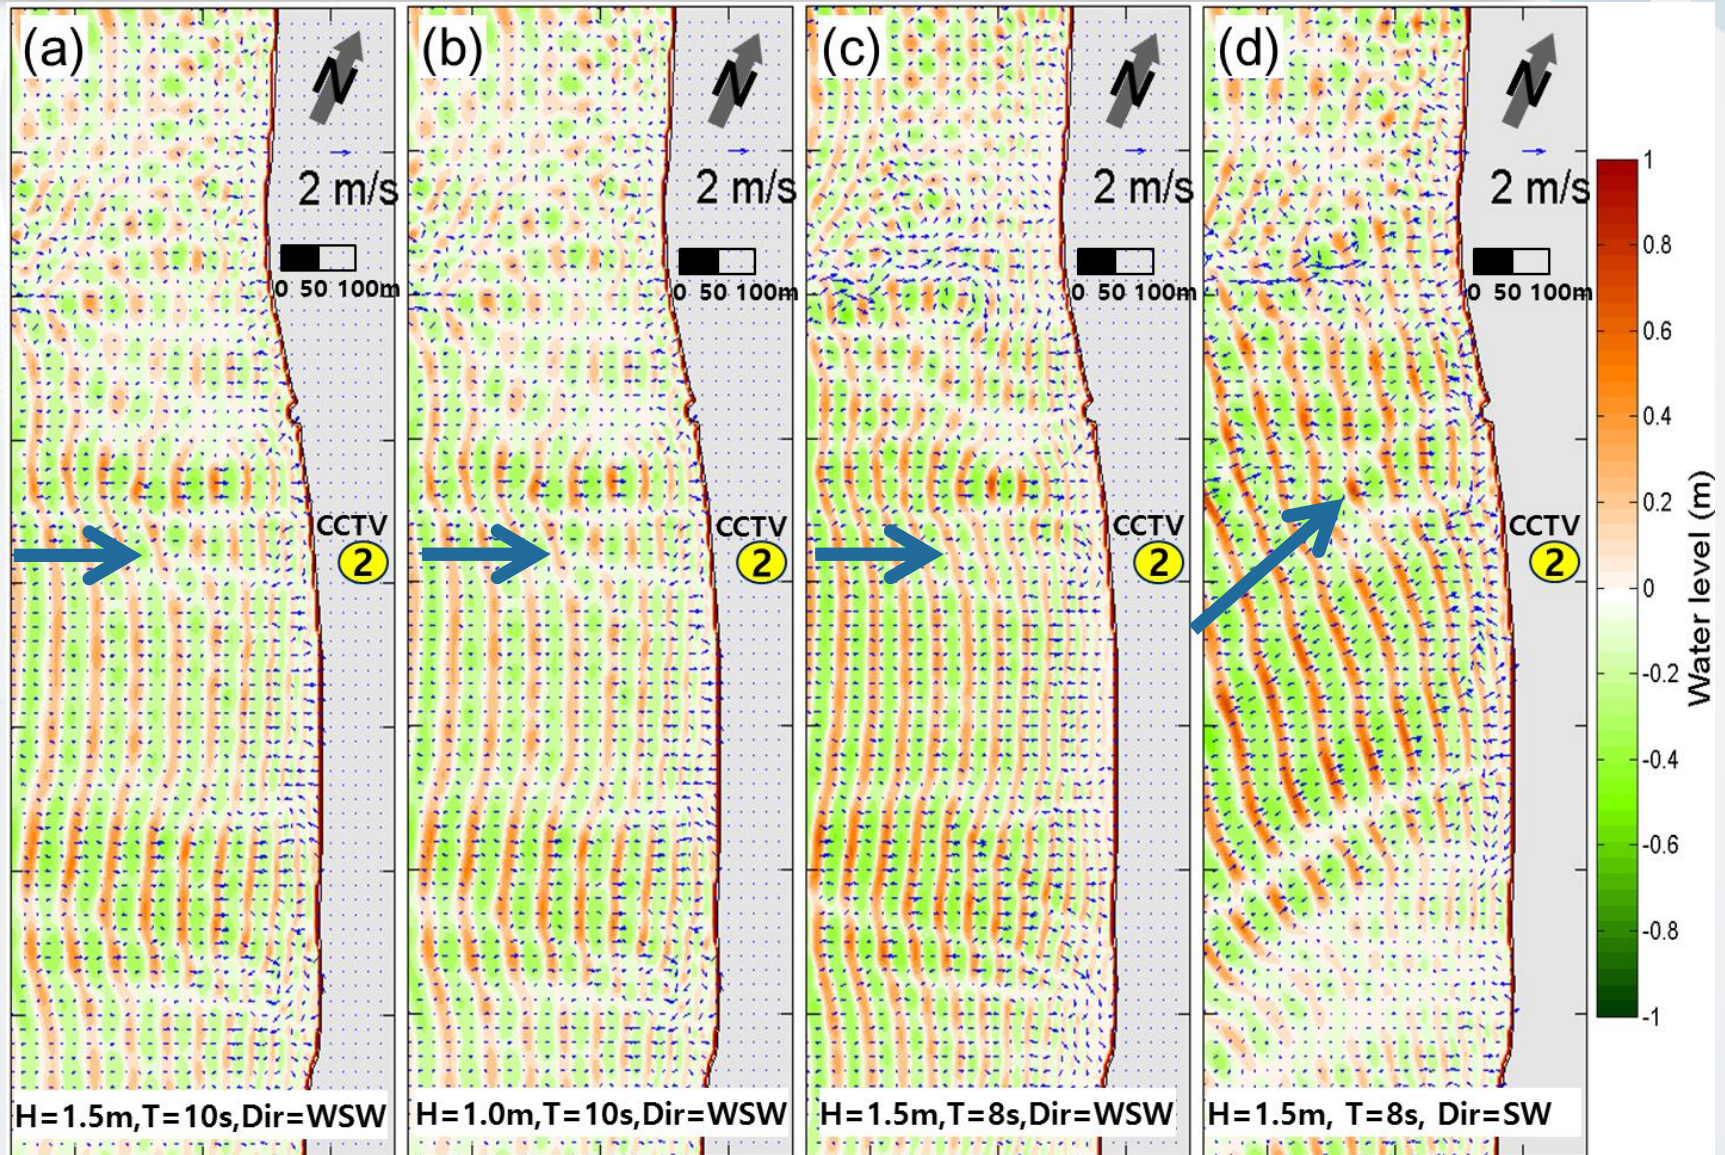

Typical rip current case : $H_s=1.5\text{m}$, $T_p=10\text{s}$, $D_p=0^\circ$

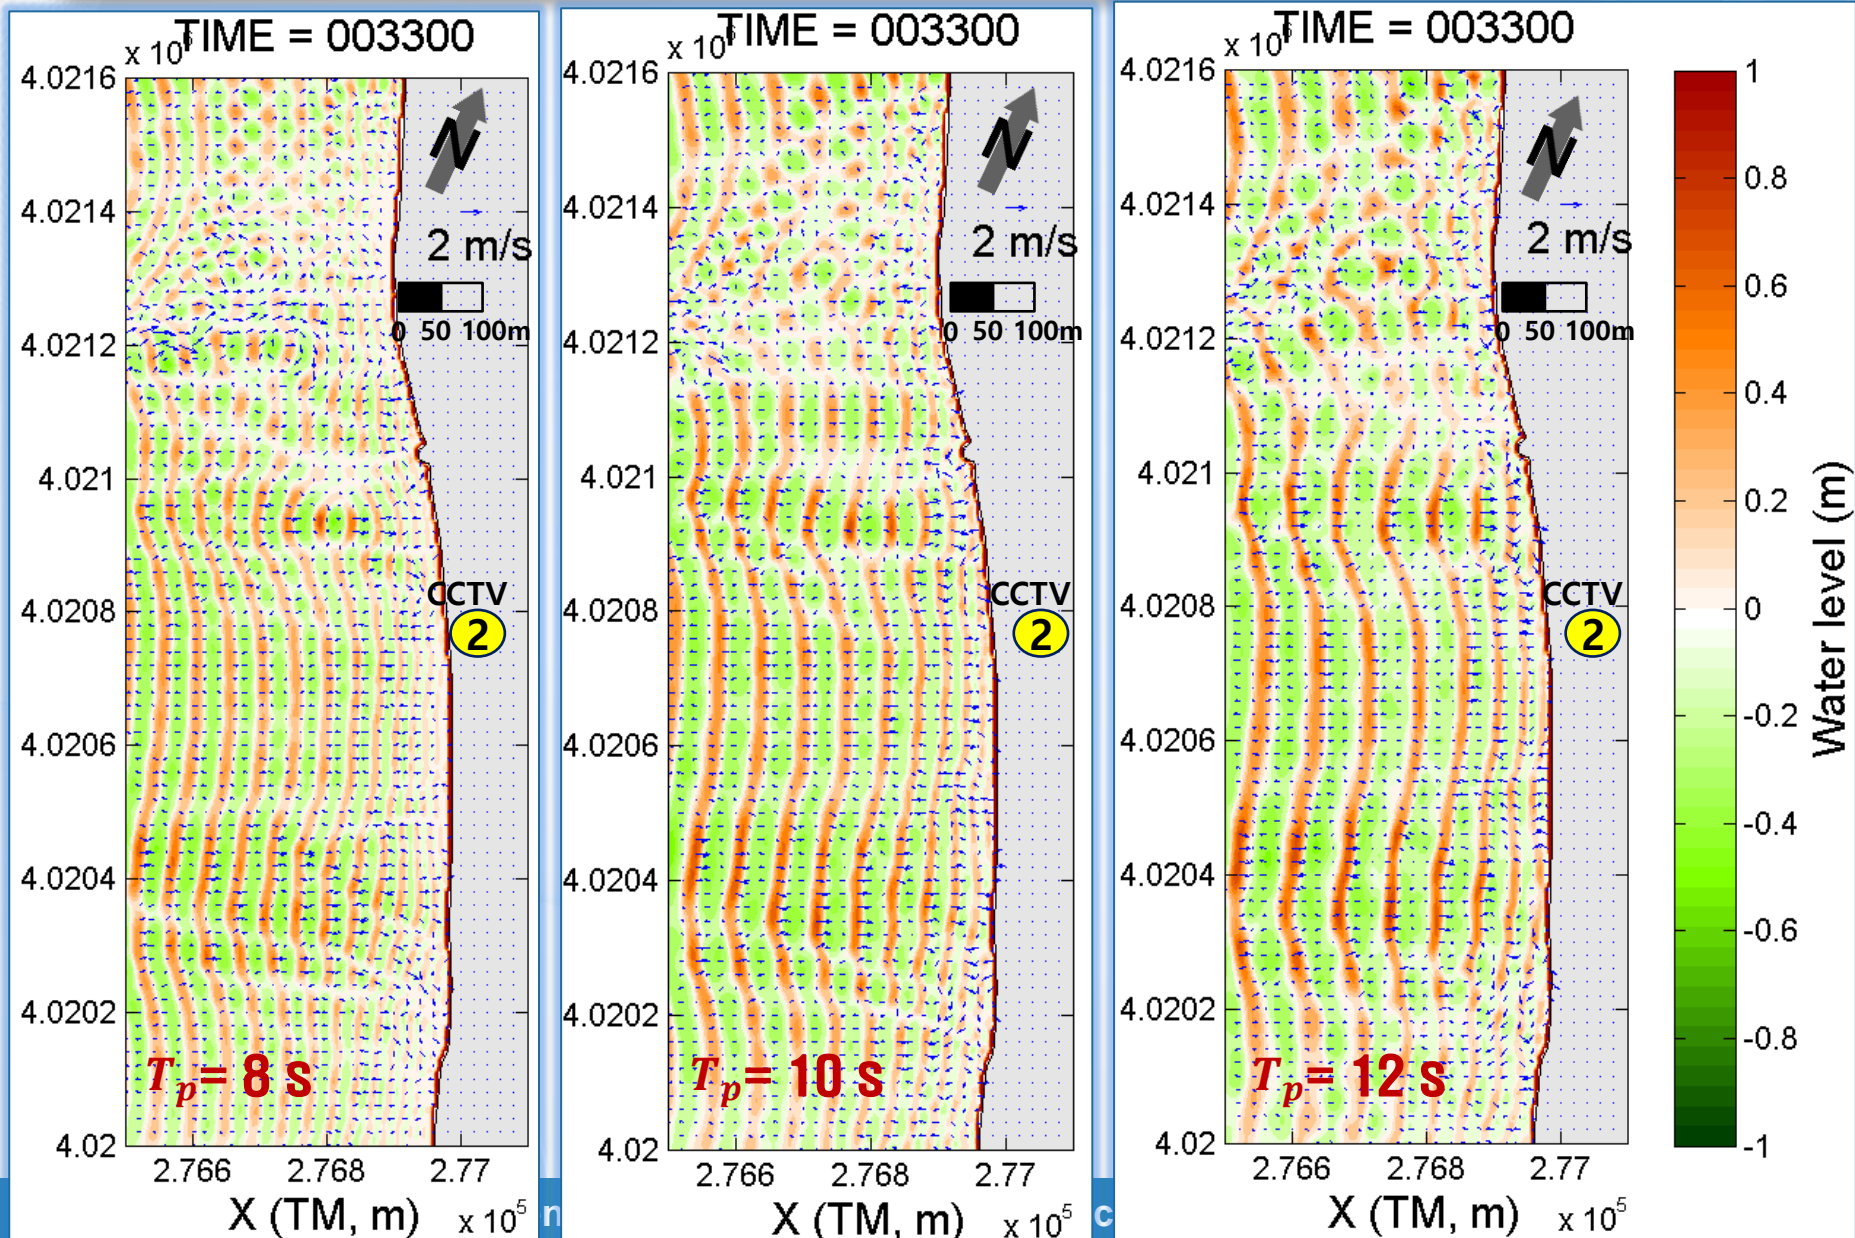

Typical rip current case : $H_s=1.5\text{m}$, $T_p=10\text{s}$, $D_p=0^\circ$

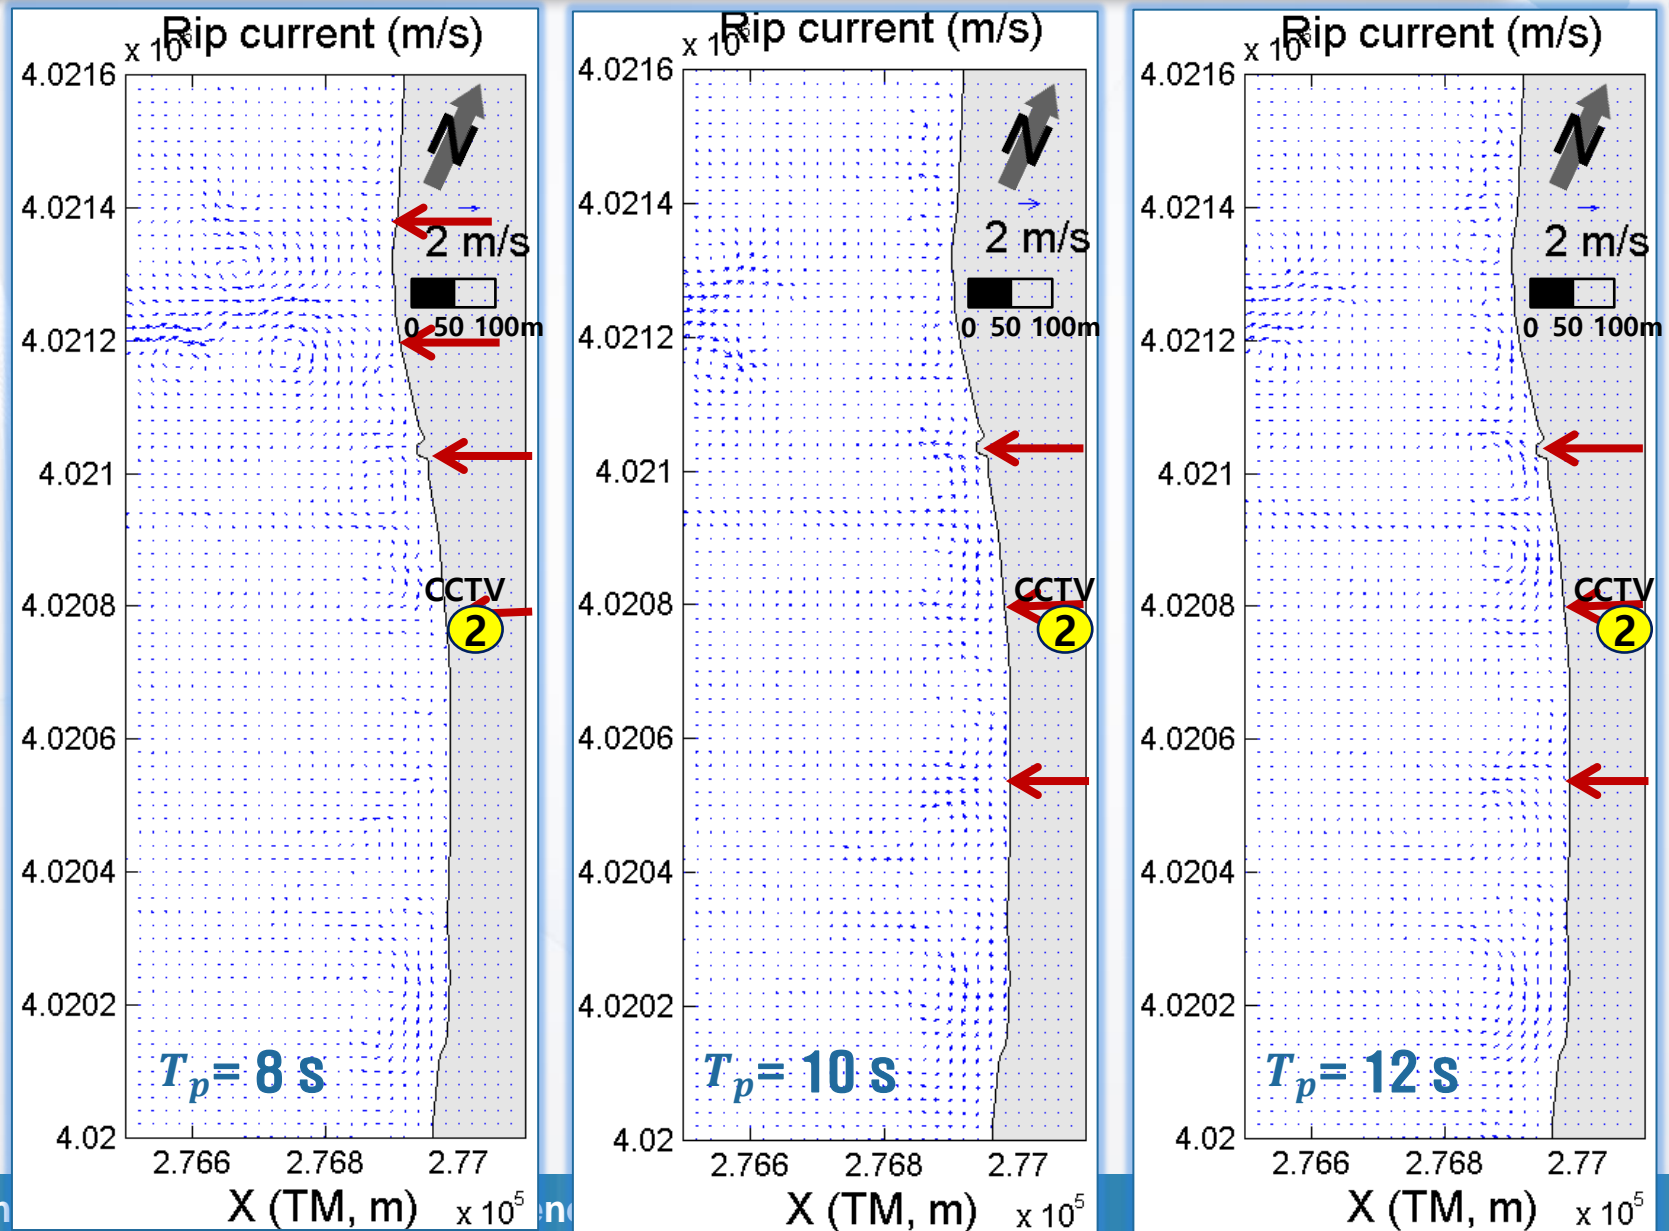

Influence of Incident wave height, period, direction

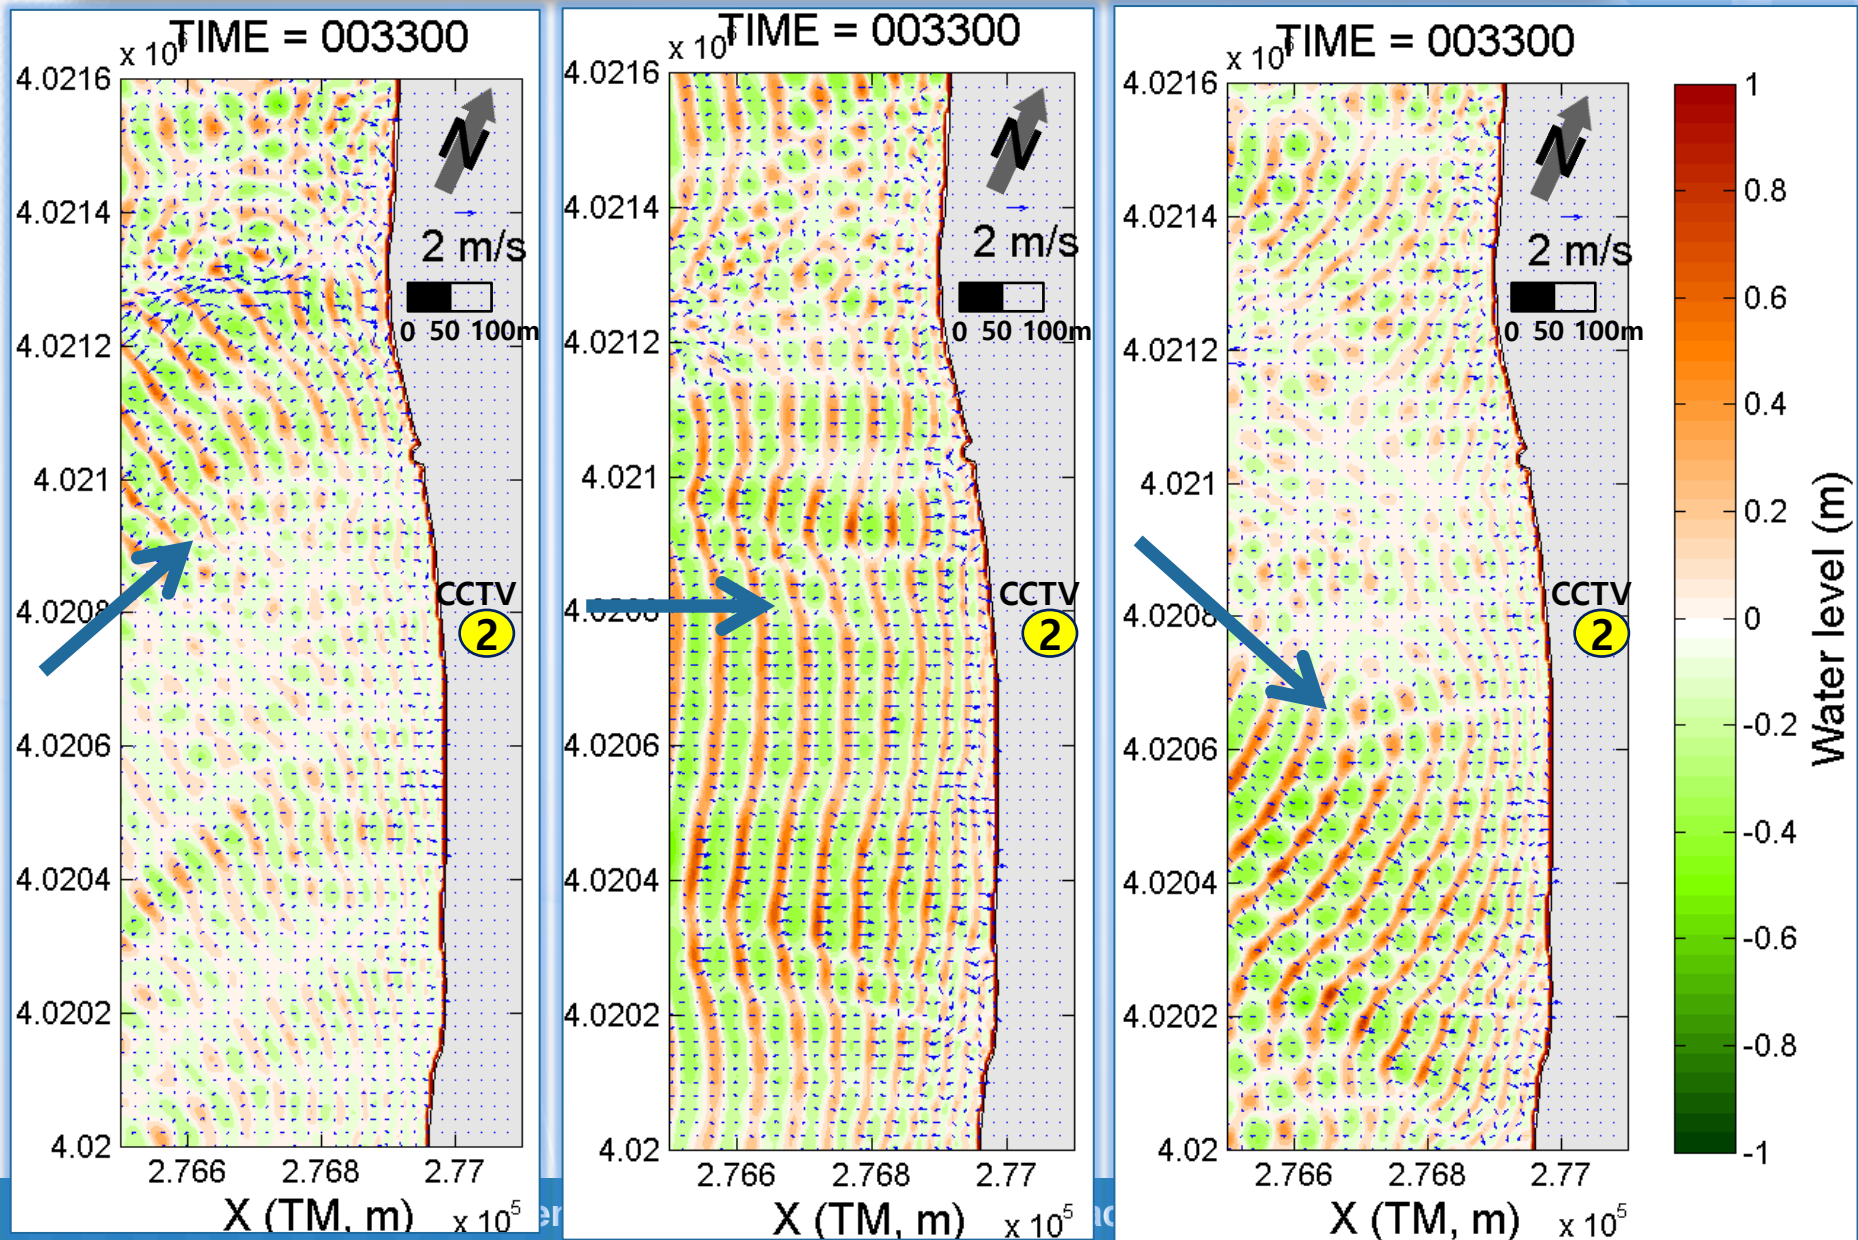

Influence of Incident wave period : $T_p = 8, 10, 12$ s

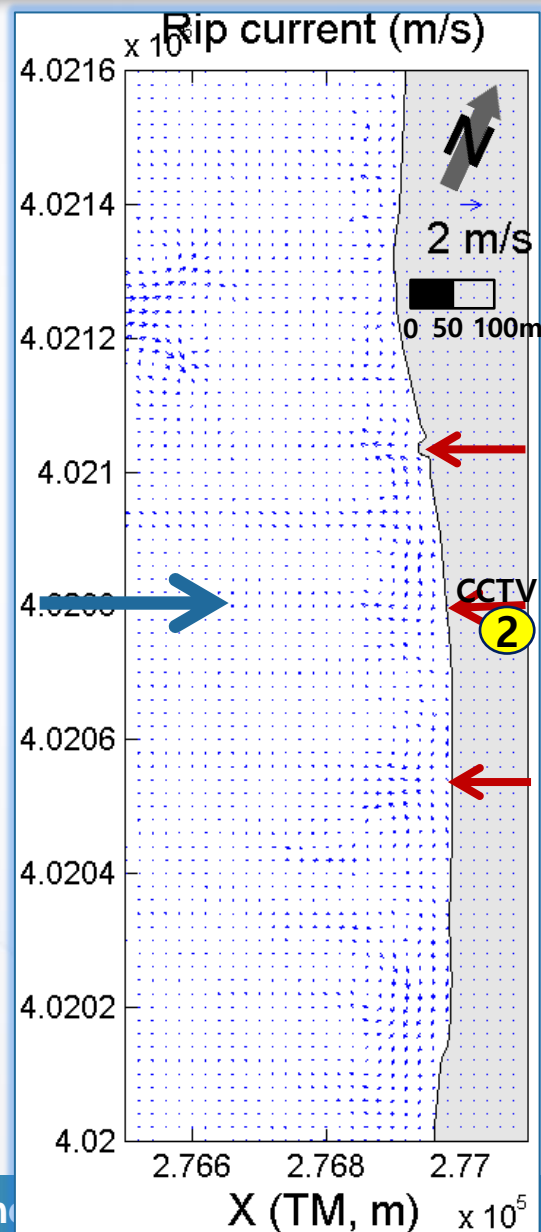

Influence of Incident wave period : $T_p = 8, 10, 12$ s

Influence of Incident wave dir. : $D_p = 45^\circ, 0^\circ, -45^\circ$

Influence of Incident wave dir.: $D_p = 45^\circ, 0^\circ, -45^\circ$

4

Discussion

Discussion

- The model results showed reasonable agreements with previous recorded report in this area.
- In our results, rip currents were increased for the higher wave heights, the longer wave periods conditions. In case of wave directions, rip channels are significantly affected by Incident wave directions.
- Estimation of the statistical likelihood of hazardous rip currents is on going now.
- Many observation data is required to calibrate accuracy of simulation results.
- Further validation and numerical testing to assess possible tuning of model coefficients will continue with the field data.
- For the future works, we can utilize this study's numerical results in a scenario-based rip current prediction system.

The background is a light blue gradient. In the top right corner, there is a cluster of semi-transparent, 3D hexagonal shapes. A large, flowing, wavy blue line with a slight glow effect curves across the lower half of the image. Below this line, the bottom portion of the image features a dark blue background with vertical stripes.

THANK YOU
